- 8 Ratio-based Type System Over Multisets

Type Inference for Ratio Control Multiset-Based Systems

(4 伊下) イヨト イヨト

- All known producer-consumer models are extensions of the standard theory of predator-prey interactions described by Lotka and Volterra.
- Recently, in order to model more faithfully the interactions in such systems, the Lotka-Volterra model was extended with ratio-dependent interactions.
- However, these models are usually described by differential equations and do not explicitly track the quantities neither in the producer/consumer nor in the environment.

### Introduction

- Multiset-based formalisms are motivated by quantitative evolutions of various systems.
- In many biological systems a reaction takes place only if certain ratios between given thresholds are fulfilled (e.g, in sodium/potassium pump and ratio-dependent predator-prey systems).

B.Aman; G.Ciobanu

Type Inference for Ratio Control Multiset-Based Systems

- The sodium-potassium exchange pump that is a transmembrane transport protein that establishes and maintains the appropriate internal concentrations of sodium and potassium ions in cells.
- Under certain conditions,  $Na^+$  and  $Ca^{++}$  ions enter the cells because of the higher concentration outside the cell, while  $K^+$  ions exit the cell due to the higher concentration inside the cell.
- Several multiset rewriting systems are used to describe the dynamics of such systems which involve parallelism and concurrent access to resources.
- Petri nets and membrane systems represent good examples of multisetbased formalisms.

・ロト ・ 得下 ・ ヨト ・ ヨト

## Introduction

- Inspired by the functioning of these systems, we provide a discrete approach and a quantitative (multiset-based) type system involving a ratio control of the resources.
- The type checking and type inference algorithms basically will browse the systems and rules, and check or collect the type information for each rule independently.
- The membrane systems represent a formalism that has compartments enclosed by membranes, floating objects, proteins associated with the internal and external surfaces of the membranes, and built-in proteins (the pump) that transport and process chemical substances.
- The intent is to avoid errors in the definition of the formal model used to model biologic processes.

(日) (同) (日) (日) (日)

We work with terms built by means of a membrane constructor (− | −), using a set O of objects. The syntax of terms st ∈ ST is
 st ::= u | (v | st) | st st

- A pattern P is a term that may include variables from a set V:  $P ::= st \mid \langle v \ y \mid P \ X \rangle \mid P \ P.$
- A rewriting rule r is a pair of patterns  $(P_1, P_2)$ , denoted by  $P_1 \rightarrow P_2$ ,

where  $P_1 \neq \epsilon$  and  $Var(P_1) \subseteq Var(P_2)$ . A rewriting rule  $P_1 \rightarrow P_2$  states that a term  $P_1\sigma$  can be transformed into the term  $P_2\sigma$ , for some instantiation function  $\sigma$ .

・ロト ・ 同ト ・ ヨト

#### Example

Consider the depicted hierarchical nested system  $\langle ab \mid ab^2c \langle b \mid ac \rangle \rangle$  with two levels having two evolution rewriting rules  $r_1$  and  $r_2$ . Some examples of the notions defined above are given on the right part of the picture.

Terms:  $\langle ab \mid ab^2c \ \langle b \mid ac \rangle \rangle$  and  $ab^2c$ Patterns:  $\langle y \mid a X \ \langle b \mid ac \rangle \rangle$  and a XInstantiation:  $\sigma(X) = b^2c$ ,  $\sigma(y) = ab$ Rewriting rule  $r_1$ :  $aX \rightarrow acX$ Rewriting rule  $r_2$ :  $aX \rightarrow ab^2X$ 

Type Inference for Ratio Control Multiset-Based Systems

イロト イポト イヨト イヨト

- The infinite set C of contexts (ranged over by C) is given by:  $C ::= \Box | C st | \langle v | C \rangle.$
- $C_1[st]$  denotes the term obtained by replacing  $\Box$  with st in  $C_1$ .
- Given a membrane system with integral proteins and a set of rewriting rules R, the reduction semantics of the system is the least transition relation → satisfying the following rule:

$$\frac{P_1 \to P_2 \in R \quad P_1 \sigma \neq \epsilon \quad \sigma \in \Sigma \quad C \in \mathcal{C}}{C[P_1 \sigma] \to C[P_2 \sigma]}$$

 $ightarrow^*$  denotes the reflexive and transitive closure of ightarrow .

B.Aman; G.Ciobanu

Type Inference for Ratio Control Multiset-Based Systems

## A Multiset Model of Membranes

### Example

• Given all these definitions, the functioning of the Na/K pump can be now described by means of the following rules:

$$\begin{array}{rcl} r_{1} & : & \langle E_{1} \ x \mid \ Na^{3} \ X \ \rangle \rightarrow \langle E_{1} \ Na^{3} \ x \mid \ X \ \rangle \\ r_{2} & : & \langle E_{1} \ Na^{3} \ x \mid \ ATP \ X \ \rangle \rightarrow \langle E_{1}^{P} \ Na^{3} \ x \mid \ ADP \ X \ \rangle \\ r_{3} & : & \langle E_{1}^{P} \ Na^{3} \ x \mid \ X \ \rangle \rightarrow \langle E_{2}^{P} \ x \mid \ X \ \rangle \ Na^{3} \\ r_{4} & : & \langle E_{2}^{P} \ \kappa \mid X \ \rangle \ K^{2} \rightarrow \langle E_{2}^{P} \ K^{2} \ x \mid \ X \ \rangle \\ r_{5} & : & \langle E_{2}^{P} \ K^{2} \ x \mid \ X \ \rangle \rightarrow \langle E_{1} \ K^{2} \ x \mid \ P_{i} \ X \ \rangle \\ r_{6} & : & \langle E_{1} \ K^{2} \ x \mid \ X \ \rangle \rightarrow \langle E_{1} \ x \mid \ K^{2} \ X \ \rangle$$

- if we have an initial membrane  $\langle E_1 \mid ATP^3 \; Na^8 \; K^2 \rangle Na^9 \; K^5$  by applying twice the above rules we reach a system  $\langle E_1 \mid ATP \; ADP^2 \; P_i^2 \; Na^2 \; K^6 \rangle Na^{15} \; K^1$ .
- So the system keeps sending *Na* outside the cell and *K* inside regardless of any known ratio thresholds (by lab experiments).
- But this is not how a biological cell works!

- Type theory has been used in biological formalisms in order to transfer the complexity of biological properties from evolution rules to types (e.g., CLS by Dezani).
- The syntax of types is simple, easy to understand and use, and these aspects make types ideal for expressing general constraints.
- The behaviour of typed terms can be controlled by a type system in order to avoid unwanted behaviours.
- According to [Kennedy, 1986], the evolution of a healthy cell ensures that the ratio between objects (e.g.,  $Na^+/K^+$ ) of a cell is kept between certain values.
- We investigate the application of type systems to the previously defined model.

< ロト ( 同 ) ( 三 ) ( 三 )

- Each object a in O is classified with an element of T (set of basic types); Γ denotes this classification.
- For each ordered pair of basic types (t<sub>1</sub>, t<sub>2</sub>), the existence of one function is assumed: min : T × T → (0, ∞) ∪ {◊}.
- We consider that the maximum ratio between  $t_1$  and  $t_2$ , denoted by  $max(t_1, t_2)$  could be determined using the relation  $min(t_1, t_2) \cdot max(t_2, t_1) = 1$ . Giving this relation in what follows we use only the *min* function.
- min(t<sub>1</sub>, t<sub>2</sub>) = ◊ means that this function is undefined for the pair of types (t<sub>1</sub>, t<sub>2</sub>). Biologically speaking, the ratio between the types t<sub>1</sub> and t<sub>2</sub> is either unknown, or can be ignored.

イロト イポト イヨト イヨト

We consider only local properties: the objects influence each other only if

- they are present inside the same membrane;
- they are on sibling membranes;
- one is present inside and the other is on the membrane;
- one is present outside and the other is on the membrane.

### Definition (Consistent Basic Types)

A system using a set of basic types T and the function *min* is consistent if:

$$\forall t_1, t_2 \in T, \ min(t_1, t_2) \neq \diamond \text{ iff } min(t_2, t_1) \neq \diamond;$$

## Ratio-based Type System Over Multisets

#### Example

- Let us assume a consistent system, the function:  $min(t_1, t_2) = \begin{cases} 0.6 & \text{if } t_1 = t_{Na} \text{ and } t_2 = t_K \\ 0.25 & \text{if } t_1 = t_K \text{ and } t_2 = t_{Na} \\ \diamond & \text{otherwise} \end{cases}$ and the previous set of rules, the well-formed term  $[ATP^3 \ Na^8 \ K^2]_{E_1} Na^9 \ K^5$ is rewritten in a well-formed term  $[ATP^3 \ Na^8 \ K^2]_{E_1} Na^9 \ K^5 \Rightarrow^* [ATP^2 \ ADP \ P_i \ Na^5 \ K^4]_{E_1} Na^{12} \ K^3.$ • Another rule cannot be applied because we would obtain terms that
  - are not well-formed.

## Conclusion

- In order to model more faithfully the interactions in producer-consumer systems, the Lotka-Volterra model was extended with ratio-dependent interactions.
- In particular the sodium/potassium pump extrudes sodium ions in exchange for potassium ions only if the ratios of these elements are between certain lower and upper bounds.
- To properly cope with such constraints, we introduce a ratio-based type system over multisets.
- We proved that if a system is well-typed and an evolution rule is applied, then the obtained system is also well-typed.
- We provided a type inference algorithm for deducing the type of each term in the multiset framework, and prove the soundness and completeness results for this type inference.
